MistriMulti

Made

Implemented in the current project. Validation includes native transport tests and Windows game checks with simulated peers; a full two-computer playtest is still required.

Assembly networking
Original NASM helpers for Windows and Linux. Direct IPv4/UDP hosting supports one host and up to seven guest slots. Includes packet fragmentation, retries, duplicate/replay rejection, heartbeats and disconnect handling. No paid relay is required.

Visible remote players
Remote characters appear in the same location, with interpolated movement, facing, outfits and animations. Room changes hide and recreate them correctly. The flicker fix was visually confirmed.

Guest customization
New guests use the native character creator. Appearance is saved independently, and returning guests can restore their hosted-world character without creating it again.

Stable player records
Steam IDs identify local players when available; a persistent local ID is the fallback. The host stores separate records per player and world. Changing a network slot does not change the character.

Core progress storage
Host records include inventory, equipment, money, health, stamina, mana, skill XP, perks, spells, appearance and basic NPC relationship data. Changed guest progress is checkpointed about every five seconds and confirmed after host storage. Backups and reconnect restoration are implemented.

Terrain and save protection
Host-controlled tilling and watering, conflict correction and bounded terrain snapshots are implemented. Guest native saves are blocked during multiplayer. These safeguards are narrower than complete solo-save isolation.

Project setup
Build/install launchers, F8 connection status, test scripts and technical documentation are present. A noncommercial license requires written permission for commercial use of any part.

MistriMulti

Half done

These systems have working foundations, but their remaining parts are necessary before they can be treated as complete.

Solo-save isolation and multiplayer entry
The installed guest save guard blocks writes, but joining still begins from a local world. A separate session/menu draft exists only in the working staging folder: temporary guest worlds, private host copies and Multiplayer buttons. It is not integrated, compiled, installed or tested; known draft issues remain. The current host still saves its loaded world normally.

Personal progress and romance
Core stats and basic friendship/relationship fields persist on the host. Personal quests, recipes, cosmetic unlocks, romance scene history, marriage dates and children are not included. Independent, complete romance progression is not working yet.

Shared world
Player visibility and soil/water synchronization work. Guests still retain local objects for unsynchronized systems. A full host-world transfer and ongoing replication are missing.

Steam integration
A native assembly probe reads the local Steam identity, and records use that ID. Remote claims are not authenticated. Steam friend invitations, lobbies and Steam networking are not implemented.

Reliability and platform validation
Windows game checks and Windows/Linux transport tests pass. Real two-client play, longer sessions, WAN/VPN conditions, native Linux game integration and Steam Deck use remain untested. The latest mana-type/envelope adjustments passed compilation but have not had a live game retest.

Host authority
Terrain requests and record structures are checked. Other character progress is still client-reported; the host does not yet validate or recompute every gameplay action.

MistriMulti

Needs doing

Remaining work for the requested behavior and complete co-op. All-player sleeping is still unimplemented; only its approach has been investigated.

Finish save isolation first
Integrate and fix the session draft. Join using a temporary world; keep multiplayer host copies outside normal solo slots. Add the Multiplayer entry beside save slots and support new multiplayer worlds. Verify that joining, saving, sleeping, disconnecting and restarting leave the original solo save unchanged.

All-player sleep
Build the sleep vote system and top-right counter, such as 1/2 sleeping. Advance the day only when every connected participant is ready. Handle cancellation, disconnects, late joins, passing out, end-of-day screens and exactly one day transition for every player.

Shared storage and item ownership
Synchronize chests, inventories used for transfers, dropped items, resource collection and loot. Use host-controlled transactions so simultaneous actions cannot duplicate or lose items.

Farm and world systems
Synchronize crops, planting, harvests, buildings, animals, world objects, resources and world changes. Joining players must receive the actual host world rather than relying on their local world.

Clock and progression
Synchronize date, time, weather, NPC schedules, events, cutscenes, quests and unlocks. Separate personal progression from world progression and complete independent romance support.

Other gameplay areas
Implement combat/enemy state, mines and dungeon generation, floor transitions and rewards. Define behavior for pauses, death and other interruptions.

Connection and release checks
Add authenticated Steam identity and the intended Steam joining flow. Test two real game clients, reconnects, crashes, simultaneous actions, save recovery and long sessions. Validate native Linux/Steam Deck play and package a build with clear compatibility requirements.
